TWO PRODUCTS / INDEPENDENT SYSTEMS

Consulting intelligence. Independent publishing.

kailor and kai apply a related design language to different software problems. kailor guides discovery, evidence-based solution analysis and project decisions. kai supports the full publishing lifecycle, public reading and reader participation. The applications do not share user accounts or a database.

System boundaries

kailor	kai
React + TypeScript + Vite	React + JavaScript + Vite
Node / Express + Prisma + PostgreSQL	Node / Express + PostgreSQL + SQL migrations
Discovery / Chat / evidence / Canvas	Rich authoring / publication / public feeds
Immutable assessments and PDF export	Search, follows, comments and notifications
Opt-in Cloudflare inference with local fallback	Session security and explicit GitHub linking

kailor | consulting system

- Input: adaptive Discovery and Coffee chat serve the same project. Answers, corrections, uncertainty and explicit user decisions remain distinguishable.
- Reasoning: attributed requirements separate essential, optional and deferred scope. The assessed options include process improvement, existing software and custom development after a justified gap.
- Continuity: project-scoped conversations, evidence and resources inform current analysis. Canvas edits carry optimistic-revision checks; old report snapshots stay immutable.
- AI boundary: inference is privacy-gated, optional and budgeted. Model responses cannot silently elevate unsupported claims into confirmed business facts.

kai | publishing system

- Authoring: Tiptap JSON documents, drafts, preview, image ingestion, revision conflicts and publish/unpublish/republish lifecycle.
- Discovery: PostgreSQL full-text search, topics, reader/author follows, latest/trending/personalised feeds and 12-item keyset pagination.
- Community: persisted likes, saves, threaded discussions and deduplicated per-recipient notifications; explicit editorial moderation.
- Identity: session cookies; GitHub OAuth + PKCE is implemented with linking by consent, never by matching email alone.

TRUST BOUNDARIES / VERIFICATION

Evidence of working software, not invented deployment claims.

Each implementation is measured through its own repository tests and isolated data. The reported test numbers below are project records—not checks run by this portfolio page.

Verified engineering evidence

kailor

315 backend + 28 frontend unit tests; 162 PostgreSQL integration tests. Typecheck, build, 14-persona evaluation plus scenario and browser checks completed in the 17 October consulting-intelligence iteration report. Most AI-path tests use mocks/local fallback; a small bounded live Cloudflare probe required a further response guard.

kai

15 backend integration tests, frontend production build and lint, plus desktop/tablet/mobile authenticated and public browser journeys. GitHub consent and actual SMTP delivery were not exercised live; provider callbacks and local outbox flows were tested under controlled conditions.

Privacy, authority and access

- kailor: private project ownership, guest-session bounds, attributed source inputs, explicit confirmations, separate live Canvas state and immutable report history. Recommendations remain proposals—not purchased services.
- kai: per-user session boundaries and author/editor permissions, server-validated rich document trees, secure media ownership, origin checks, hashed tokens and recipient-scoped notifications.
- Independent data: each product has a separate PostgreSQL schema and API. Visual similarity is not evidence of shared authentication or cross-product synchronisation.

Current limitations and claims

- The portfolio schedules a 27 October 2026 launch target, but the two public website URLs have not been confirmed live; the repository links are available and the site buttons remain disabled until validated.
- kailor: commercial consultant selection, quoting, invoice/commissioning and progress tracking are product direction, not implemented commercial transactions. GitHub OAuth and arbitrary PDF/Word upload parsing are not established as live capabilities.
- kai: deployment-grade durable media storage, real GitHub provider consent, SMTP delivery, operational monitoring and public production hosting require separate verification.
