Full-Stack Productivity Platform

A React and Node.js workspace for tasks, projects, goals, notes and everyday scheduling. Separate screens share an authenticated Express API and MongoDB persistence.

01 / SYSTEM STRUCTURE

How the application is organised

01 CLIENT

React / Vite

Authenticated routes, forms and dashboard views.

02 API

Express / JWT

Protected CRUD handlers and notification writes.

03 DATA

MongoDB / Mongoose

User-owned task, project, goal and note documents.

02 / WORKSPACE

Application modules

Tasks and projects

Create, update, complete and remove work records. The overview uses the same stored data.

Notes and folders

Create, edit, archive and organise notes through folder references.

Goals, reminders and calendar

Due-date records feed planning views; the calendar joins items from several collections.

Alarms and notifications

Browser alarm checks and polled notification slideouts complement the CRUD views.

Implementation note

The repository includes source for the listed features. It does not include a committed automated test suite, a CI pipeline or evidence of a current public deployment.

Implementation and verification

Design choices, code boundaries and deployment work visible in the inspected repository.

03 / RESPONSIBILITIES

Account data and API routes

/api/auth	Registration, login, profile and account preferences
/api/tasks, /api/projects	User-scoped task and project CRUD
/api/goals, /api/reminders	Planning records and date-based work
/api/notes, /api/folders	Notes, archive actions and organisation
/api/alarms, /api/notifications	Alarm definitions and notification documents

04 / SECURITY

What the code protects - and what remains

Implemented: Passwords use bcryptjs; JWT middleware verifies protected bearer requests. Primary workspace routes use user-scoped database queries. Account preferences and profile images have dedicated endpoints.

Needs hardening: The user-list endpoint is not protected in the inspected code. Bearer tokens are kept in browser localStorage, CORS uses a broad default, and static upload serving requires further protection for production use. No live security audit is supplied.

05 / VERIFICATION

Source inspection rather than measured tests

Reviewed the React route structure, authentication context, Express route handlers, Mongoose models and project documentation. No test runner output or automated integration evidence was present in the repository, so this brief does not claim passing tests.
